20. ABSTRACT (Continue on reverse side if necessary and identify by block number) This document lists and describes the usage of the variables in the Decision-Feedback Equalizer Simulation (DFES) program which was written for the Naval Ocean Systems Center by Signatron, Inc.  The DFES program can transmit QPSK or BPSK through an hf channel. The channel can have fading, doppler and multipath. The transmission can be received and demodulated by a Decision-Feedback Equalizer with one of four weight update algorithms: Kalman, LMS, fixed, and Rake.

## INTRODUCTION

The Decision-Feedback Equalizer Simulation (DFES) program is written in FORTRAN. It simulates LMS (Least Means Squares), Kalman, Rake, and fixed tap versions of high frequency radio channel equalizers. Considerable interest in this program has been shown by other Government laboratories, industry, and universities. It was felt necessary to preserve the following information on DFES in this publication in order to ease the use and/or modification of this complex program by future users.

The material herein includes basic information on every variable in DFES including:

1. Alphabetically arranged descriptions of all variables.
2. Page numbers from the "Program Performance Specification" where more information on each variable may be found.
3. A tabular listing of all variables indicating which subprograms and routines set, use, or output each variable.
4. A listing of subroutines and functions and where they are used in the program.

This document is useful for identifying and locating variables when modifying and/or debugging the program.

In the following sections, DFES refers to the main program which precedes the initialize parameters subprogram.

D is the complex transmitted PSK digit, before encoding, returned to the Detector by DPGEN. It has the values  $\pm 1 \pm j$ . The Detector uses it to set the transmitted PSK symbol  $A=D$ . The Differential Decoder uses it in a comparison with DHAT to update the error counter ERROR.

The following process is performed twice to generate the real D(1) and imaginary D(2) parts of the complex output.

- (a) The high order bit I is extracted from MWORD.
- (b) MWORD is shifted one place to the left by extracting the low order 31 bits and multiplying the result by 2.
- (c) If the extracted bit I is a 1, MWORD is replaced by an exclusive OR of MWORD and JWORD.
- (d) For  $I = 1$ ,  $D(J) = +1$   
For  $I = 0$ ,  $D(J) = -1$ .

Number of Interpolator Samples

INT is an input parameter to the subroutine PARIN. It is an odd integer of range  $1 \leq \text{INT} \leq 11$  with a default of 5. The Initialize Parameter subprogram uses it to set the Interpolator half span interval INT1, the length NQ of the input array Q and the length NR of the receiver sample array R as follows:

$$\text{INT1} = (\text{INT} - 1)/2$$
$$NO = NTB + INT - NTR + KSET (CTAP)$$
$$NR = NTB + INT - NTR$$

In the bit symbol iteration processing it is used to set the number of additional input samples NRQ to be provided by the subroutine TAPER for IBS = 1 to NRQ = INT-NTR

The Initialize Parameters subprogram will reset INT for  $\text{INT} \leq \text{NTR}$  to  $\text{NTR}+1$  for NTR even or  $\text{NTR}+2$  for NTR odd. From that point on the value of INT remains fixed.

Parin sets INT to

### Kalman/LMS Adaptation Indicator

KLMS is an integer variable with a value of 0 or 1. Initially when NUM=1, FWATE sets KLMS=1 for NALG=1 and KLMS=0 for NALG=2. When KLMS=1, FWATE updates the weight vector W using the least mean squares algorithm. For KLMS=0, the Kalman algorithm is used. For NALG=2 FWATE leaves KLMS=0 until KNUM > KEND or KNUM=KRST when it sets KLMS=1. For each KVAR < KNUM < KEND, KLMS=0.

In the subroutine BFILT the method used to compute the array BETA depends on the value of KLMS.

### Algorithm Indicator (NALG)

NALG is the integer indicator for the adaptation algorithm used by FWATE in updating the forward filter weight vector  $w$ . The subroutine PARIN sets NALG to the following values according to the input value of ALGOR:

<u>ALGOR</u>	<u>NALG</u>	<u>Weight Adaptation Method</u>
LMS	1	Least Mean Squares algorithm
KAL	2	Kalman algorithm
FIX	3	Weights remain fixed to initialization values
RAKE	4	Rake equalizer

NALG remains constant unless the Kalman algorithm is specified (NALG = 2) and the synchronization subroutine is not used (SMODE = 1). When this occurs, the Initialize Parameters subprogram temporarily sets NALG = 3 to force a delay in the adaptation. When 2\*NTAP iterations have been completed, NALG is reset to its original input value of 2.

The Detector sets AHAT = A when NALG = 2 and REF = 3. The Detector also calls the BFILT subroutine to update BETA for NALG = 1 or 2 and LTAP > 1.

Initialize parameters sets  $NALG = 3$  if  $KALA > 0$ .

The detector sets  $NALG = ALGOR$ .

### Timing Interval

When bit synchronization is required ( $NA > 0$  and  $SMODE=0$ ), the initial value of TI is 0 and the final TI value is computed by the subroutine SYNC. If bit synchronization is not used, TI is an input parameter to the subroutine PARIN. TI is a real variable with the range

$$-1 \leq TI \leq 1$$

Once computed by SYNC or input by PARIN, TI remains constant.

Sync sets TI as

TI is used to compute the SINK array for the Interpolator subprogram.

DFES sets  $TI = 0.0$
